DESIGN GUIDELINESFuture Design Demand

To arrive at the Future Demand we have to multiply the present demand with the following factors:

1. **Growth Factor** related to the predicted growth of the population.

Growthrate 1981 (National census): 2.6%.

Assuming that the family planning efforts by HMG will have a certain measure of success, then the population growthrate will decrease. The following, fairly arbitrary, assumptions therefore lead to the overall growthfactor: F_g

$F_{g\ 10}$: First ten years, assumed annual growthrate of 2.6%

$F_{g\ 20}$: Second ten years, assumed annual growthrate of 2.0%

The total growthfactor will then become:

$$F_g = F_{g10} * F_{g20} = 1.026^{10} * 1.020^{10} = 1.29 * 1.22 = 1.57 = F_g$$

2. **Consumption Increase.** In twenty years time a lot can change. The change in hygienic pattern and possibly in improvement of economic conditions may lead to an increase in the daily water consumption per person. Since a few years the Central Public Health Engineering and Environmental Organisation of the Ministry of Housing and Public Works in New Delhi, India has advised its chief engineers in the states to increase the daily design water consumption per head from 10 gallons to 15 gallons, i.e. from 45 to 70 liters. Such an increase we, in Nepal, can at present not afford ourselves. All the same an increase from 45 to 60 per person per day in twenty years time seems reasonable. This leads to another factor, due to the increase of the consumption: F_c

$$F_c = 60/45 = 1.33$$

3. **Wastage and Leakage.** One unavoidable fact of life in a water supply scheme is the wastage and leakage of water. Obviously, through design, maintenance and tapstand supervision one can hope to reduce the spilling of water. However experiences in other countries show that it is necessary to calculate with a factor for wastage and leakage. Assuming this leakage to be only 10% of the total daily demand leads to a factor: F_l .

$$F_l = 1.1$$

Taking all the various factors into account, we can calculate the total future demand in the following way:

$$\text{FUTURE DEMAND (FD)} = F_g * F_c * F_1 * \text{PRESENT DEMAND (PD)}$$

$$\text{or FD} = 1.57 * 1.33 * 1.1 * \text{PD} = 2.3 \text{ PD}$$

The increase factor then totals : $F_{\text{tot}} = 2.3$

4. Peakfactor

For closed systems the following water consumption pattern is assumed (reference 3.1.5 of 1980 standardisation on storage tank sizing).

Hours of the day	Consumption in % of daily demand
5.30 a.m. - 8.30 a.m.	40%
8.30 a.m. - 4 p.m.	20%
4 p.m. - 7 p.m.	35%
7 p.m. - 5.30 a.m.	5%

This consumption pattern is based on assumptions and not on actual studies. All the same the daily pattern of activities in the hill districts supports this assumed consumption pattern sufficiently to justify the above division. Taking however these figures not too rigidly, one can say that during the morning and evening hours about 75% of the daily consumption has to be supplied. This amount then has to be supplied in about five to six hours. Thus, we have to also calculate the distribution in such a way that it actually can deliver the required quantity. This means that a peakfactor has to be introduced for periods of high demand.

- Assuming that 75% of the daily demand has to be supplied in six hours, we can obtain the peakfactor through the following:

$$F_p = 24 \text{ hrs} / 6 \text{ hrs} * 0.75 = 3.0$$

or, the distribution system has to be calculated for a maximum flow of $3.0 * Q_{\text{average}}$.

In the case of an **open system** the following peakfactor can be assumed as :

$$F_p = 2.0$$

N.B. To avoid unnecessary wastage this factor is reduced in comparison to the factors used in a closed system. Note that it is common practice in our office to design closed systems as these can be operated more reliably. However a small system not longer than 5 km including the distribution system could be designed as an open system.

The following example illustrates the working of the above factors:

TAP NUMBER	HOUSES	POPULATION ⁴⁾	WATER CONSUMPTION		FLOW (l/s)	PEAKFLOW (l/s) ³⁾
			2043 ¹⁾	2063 ²⁾		
Tap 1	23	161	7245	16663	0.19	0.57
Tap 2	12+school	84+100st	3780+1000 ⁵⁾	8694+2000 ⁶⁾	0.10+0.02	0.32
Tap 3	30	210	9450	21735	0.25	0.75
Tap 4	16	112	5040	11592	0.13	0.40
Tap 5	28	196	8820	20286	0.23	0.69
Tap 6	19+healthpost	133	5985+ 500 ⁷⁾	13765+2000 ⁸⁾	0.16+0.02	0.50
Total (l/s)					1.10	3.23

- Notes. 1) Daily consumption 2043: 45 liters per person/day
 2) Daily consumption 2063 : total of 2043 multiplied by $F_{tot} = 2.3$
 3) Peakflow = $Q * F_p = Q * 3.0$
 4) Population: seven inhabitants per household is assumed
 5) School: 10 l per student per day
 6) Doubling of total consumption in the school in 20 years
 7) Health Post : 500 l per day (2043)
 8) Health Post : 2000 l per day (2063)

In the case of 6) and 8) an average water consumption during the day is assumed, or a peakfactor of 1.0 ($F_p = 1.0$)

Calculation of reservoir size (roughly):

$$\begin{aligned} \text{Tank outflow}^{1)} & Q * F_p * 3 * 3600 = 3.24 * 3.0 * 3600 = 34992 \\ \text{Tank inflow} & Q * 3 * 3600 = 1.10 * 3.0 * 3600 = 11880 \\ \text{Tank size required} & = 23112 \text{ l} \\ & \text{or } 23.1 \text{ m}^3 \end{aligned}$$

A reservoir of 23 m^3 will thus be sufficient.

If we decide to build a reservoir for the first ten years only a tank of 12 m^3 is sufficient as is shown in the following calculation.

$$\begin{aligned} \text{Tank outflow } Q_{10}^{2)} * F_p * 3 * 3600 & = 0.75 * 3.0 * 3 * 3600 = 24300 \\ \text{Tank inflow } Q * 3 * 3600 & = 1.10 * 3 * 3600 = 11880 \\ \text{Tank size required} & = 12420 \text{ l} \\ & \text{or } 12 \text{ m}^3 \end{aligned}$$

- NOTES:
- 1) inflow versus outflow during the three peak hours
 - 2) Q_{10} : demand in l/s in 10 years : 0.75 l/s (see annex I)
 - 3) It is assumed that the reservoir tank is completely full at 5.30 a.m. and completely empty three hours later, at 8.30 a.m.
 - 4) A second tank of 11 cu.m. can be built after 10 years to cover the demand of the second ten year of the service life of the system. Such an approach is not only financially attractive because of the reduction of the cost of initial investment and interest, but also provides the opportunity to place the tank nearer to the place where increased consumption is to be expected.

The same situation for an **open system** leads to a slightly different calculation ($F_p = 2.0$).

TAP NUMBER	HOUSES	POPULATION	WATER CONSUMPTION		FLOW PEAKFLOW	
			2043	2063	(l/s)	(l/s)
Tap 1	23	161	7245	16663	0.19	0.38
Tap 2	12+school	84+100st	3780+1000	8694+2000	0.10+0.02	0.22
Tap 3	30	210	9450	21735	0.25	0.50
Tap 4	16	112	5040	11592	0.13	0.26
Tap 5	28	196	8820	20286	0.23	0.46
Tap 6	19+healthpost	133	5985+500	137665+2000	0.16+0.02	0.34
Total (l/s)					1.10	2.16

- N.B.
- 1) It should be noted that it is cheaper to lay a slightly larger pipe now if so required, than to lay an extra or bigger size pipe in ten years time.
 - 2) Consequently, pipeline systems should be designed for the predicted flow of twenty years ahead. Additional tanks or intakes can be built after ten years at little extra cost. Through such a procedure we decrease the initial investment in cash and time, thus possibly enabling the project to serve more project communities.
 - 3) In special cases, when there are for instance no alternative watersources around to augment the present inadequate supply the responsible engineer can decide to assume a future consumption per day of 45 l only. (instead of 60). In such a case, (F_{tot}) equals 1.73.
 - 4) High peak flows at tapstands will sometimes require more than 1 tap to discharge the flow. Although this at present may not be feasible in all cases it should still be kept in mind that this flow may need to be delivered in the near future. Thus, the distribution pipe line needs to be calculated for this flow and adequate provisions at the tapstand need to be incorporated right at the design time.

General Notes on the Standardization 2043/44

Last year the 2041/42 standardisation was revised due to the introduction of standard norms and measurement book in the process of preparation & construction work of the community water- supply and sanitation projects.

The major change in that revision was the introduction of quantity of different items of work instead of materials. This year changes in the different structures have been included. Furthermore for each structure a breakdown of the materials is given in order to facilitate the work of cost estimation.

In addition to the estimates given in the next pages, the following general notes should be observed:

- Each project should receive 3 m wiremesh 1mm and 3m wiremesh 4 mm for sieving cement and sand respectively. After use this wiremesh can be used for preparation of tanks, BPT etc. and for sanitation. This wiremesh should be added to the estimate.

- Tools

The tool list provided in pages 9 through 11 are guidelines. Depending on the circumstances it is possible to change the quantities given. However a brief explanation in writing will be required why the changes are necessary.

- Catchment

For the stream and spring catchment only the collection chamber and valve chamber have been standardized. During detail survey, the overseer or engineer has to make a sketch of the spring, Kholsi or Khola. On the basis of this sketch additional structures for the spring or stream catchment should be designed. These should be estimated separately and added to the estimate of the catchment.

- Village contribution

The village contribution for stones, gravels and trenchdigging and earthwork of various units of the project should be calculated according to the standard Norms sent by Ministry of Panchayat and Local Development, Pulchowk.

- Sanitation

School/Healthpost latrines are to be included in the estimate on the basis of one room per students, or users in the case of a healthpost.

As a rule the following can be used to derive the number of rooms of a set of latrines:

School less than 100 students	-	1 room
Health Post	-	1 room
School 100-200 students	-	2 rooms
Big Health Post	-	2 rooms
School 200-300 students	-	3 rooms
School 300-400 students	-	4 rooms

More than 4 rooms will not be provided in a school. In very large school a separate 1 pit box latrine can be provided the teachers.

It should be noted that although a set of latrine is included in the estimate, these will only be built when the headmaster, the school committee or the health-post-incharge have specifically asked for their construction in writing. Until such a request is received no latrines are to be constructed.

For the latrines a new standardisation is underway and will be printed later in a separate booklet. Until then the standardisation used up to now will be valid.

Design

The design of a system is to be made according to the note on this subject dated September 1982. A diversion from these design rules is only allowed after the approval of the Project Manager.

The present design procedure is as follows:

<u>Phase</u>	<u>Done by</u>	<u>Checked by</u>
Survey calculations	overseer	engineer
Profile (draft)	overseer	engineer
Design (draft)	engineer	Project Manager
Profile/design drawing (final)	overseer	engineer
Estimate	overseer	engineer
Technical approval	Project Manager	
Approval	Director	

Original File

The original file should contain the following informations:

- . preliminary survey report
- . survey calculation sheets
- . calculation of (peaks) flow for each tap
- . hydraulic calculation sheets
 - In case more than one possibility was calculated, indicate clearly which one was selected.
- . sketch and quantity estimate of additional structures for spring or stream catchment.
- . map like sketch of the supply area indicating easily recognisable points (temple, bridge, peepal tree)
- . blueprint of final design with profile and HGL and flowdiagram of system. (indicating flows only)
- . relevant correspondence.

ANNEX I

Calculation of Q_{10}

Q_{10} is the daily demand in l/s after ten years
 Q_{10} can be calculated in the same way as the Q_{20} of 1.10 l/s mentioned earlier. It can also be calculated in a slightly simpler way. But then we have to redefine some of our assumptions. It was stated that

$$F_{tot} = F_g * F_c * F_1$$

If we want to use the same formula for the first ten years, we only have to rewrite the formula as follows:

$$F_{tot} = F_{g10} * F_{c10} * F_1 = 1.29 * 1.11 * 1.1 = 1.58$$

$F_{g10} = 1.29$ (refer to 1. Growth Factor)

F_1 : leakage and wastage are not assumed to change

F_{c10} : an increase of 45 to 50 liter per person per day is assumed in ten years, or $F_{c10} = 1.1$

The daily demand after ten years can now be calculated as follows:

$$Q_{10} = \frac{F_{tot\ 10}}{F_{tot}} * Q_{20} = \frac{1.58}{2.30} * 1.10 \text{ l/s} = 0.75 \text{ l/s}$$

Reduced Increase Factor F_{tot}

As mentioned on page 5, note 3) in special cases it might be necessary to reduce the assumed future consumption. There are two possibilities to do so.

1) The future consumption per day and person is assumed as 45 l only instead of 60 l. The total increase factor becomes then:

$$F_{tot} = F_g * F_c * F_1 = 1.57 * 1.0 * 1.1 = 1.73$$

2) According to National Census in some districts the population growthrate is not 2.6% but as low as 0.5% (Syangja & Palpa). This is due to population drain. In these cases if necessary the total increase factor can be reduced by taking in count the individual growth factors (population) of the districts.

<u>Districts:</u>	<u>Growthrate:</u>	<u>Growth Factor:</u>	<u>Total Increase Factor</u>
Normally	see side 1	1.57	$1.57 * 1.33 * 1.1 = 2.30$
Syangja, Palpa	0.5 %	1.1	$1.10 * 1.33 * 1.1 = 1.61$
Gulmi, Parbat	1.0 %	1.22	$1.22 * 1.33 * 1.1 = 1.78$
Lamjung	1.5 %	1.35	$1.35 * 1.33 * 1.1 = 1.98$

Note: These reduced increase factors may be used only in special cases. In ordinary cases the factor $F_{tot} = 2.3$ has to be applied
